

The global response of terrestrial protected area biodiversity to human impacts

Claudia Gray, Samantha Hill, Tim Newbold, Lawrence Hudson, Luca Börger, **Andy Purvis** & Jörn Scharlemann

Questions

- How effective are terrestrial Protected Areas in retaining site-level biodiversity?
- Do Protected Areas work solely by reducing pressures, or do they also mitigate responses?
- What attributes of Protected Areas matter?

Spatial

tside

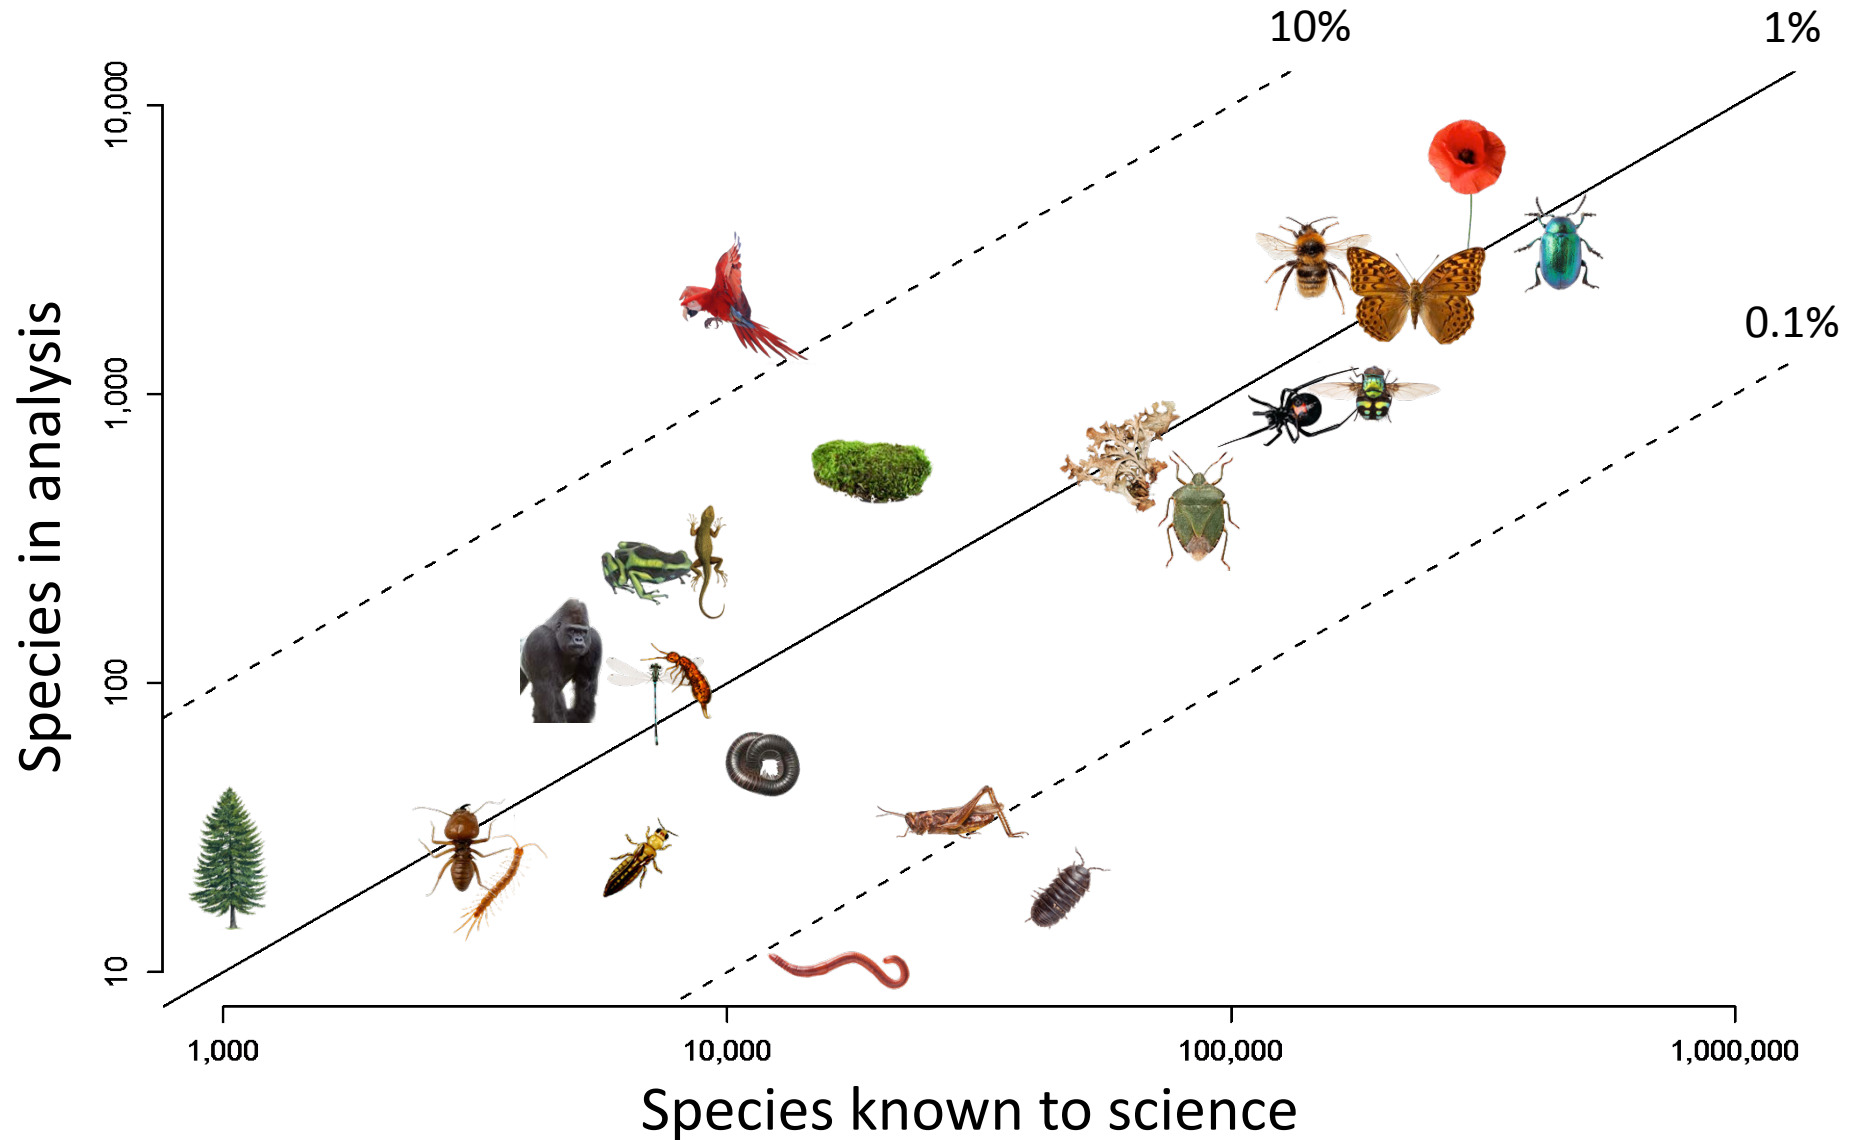

8,685 sites
50 countries
100 ecoregions

126 published sources
192 data sets
1,107,009 samples

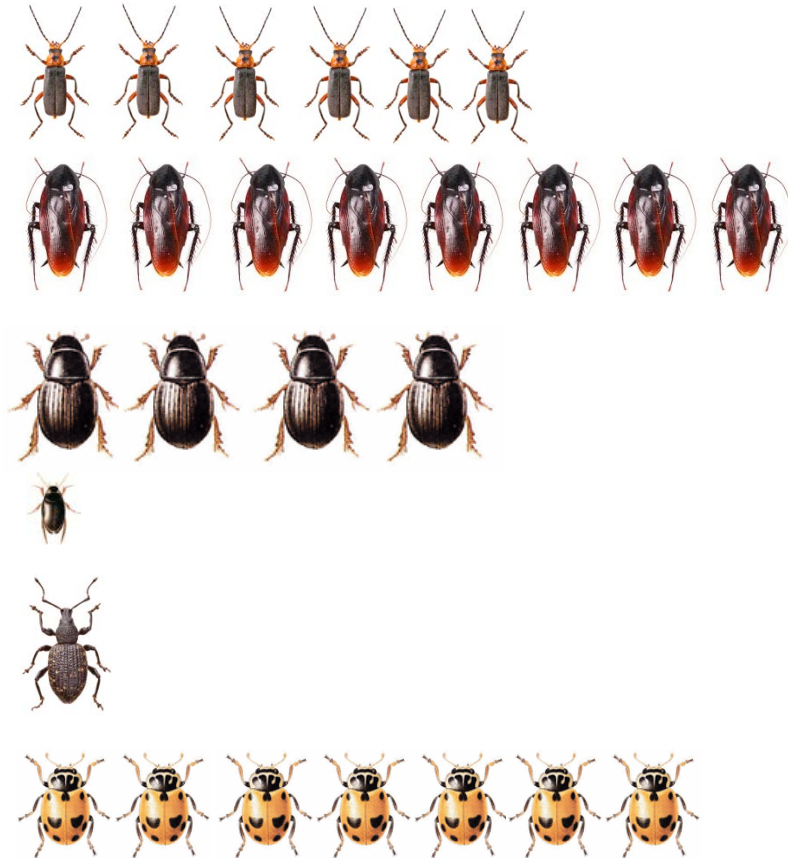

18 hotspots
467 protected areas
17,500 taxa

Taxonomic representativeness

Richness, abundance & endemism

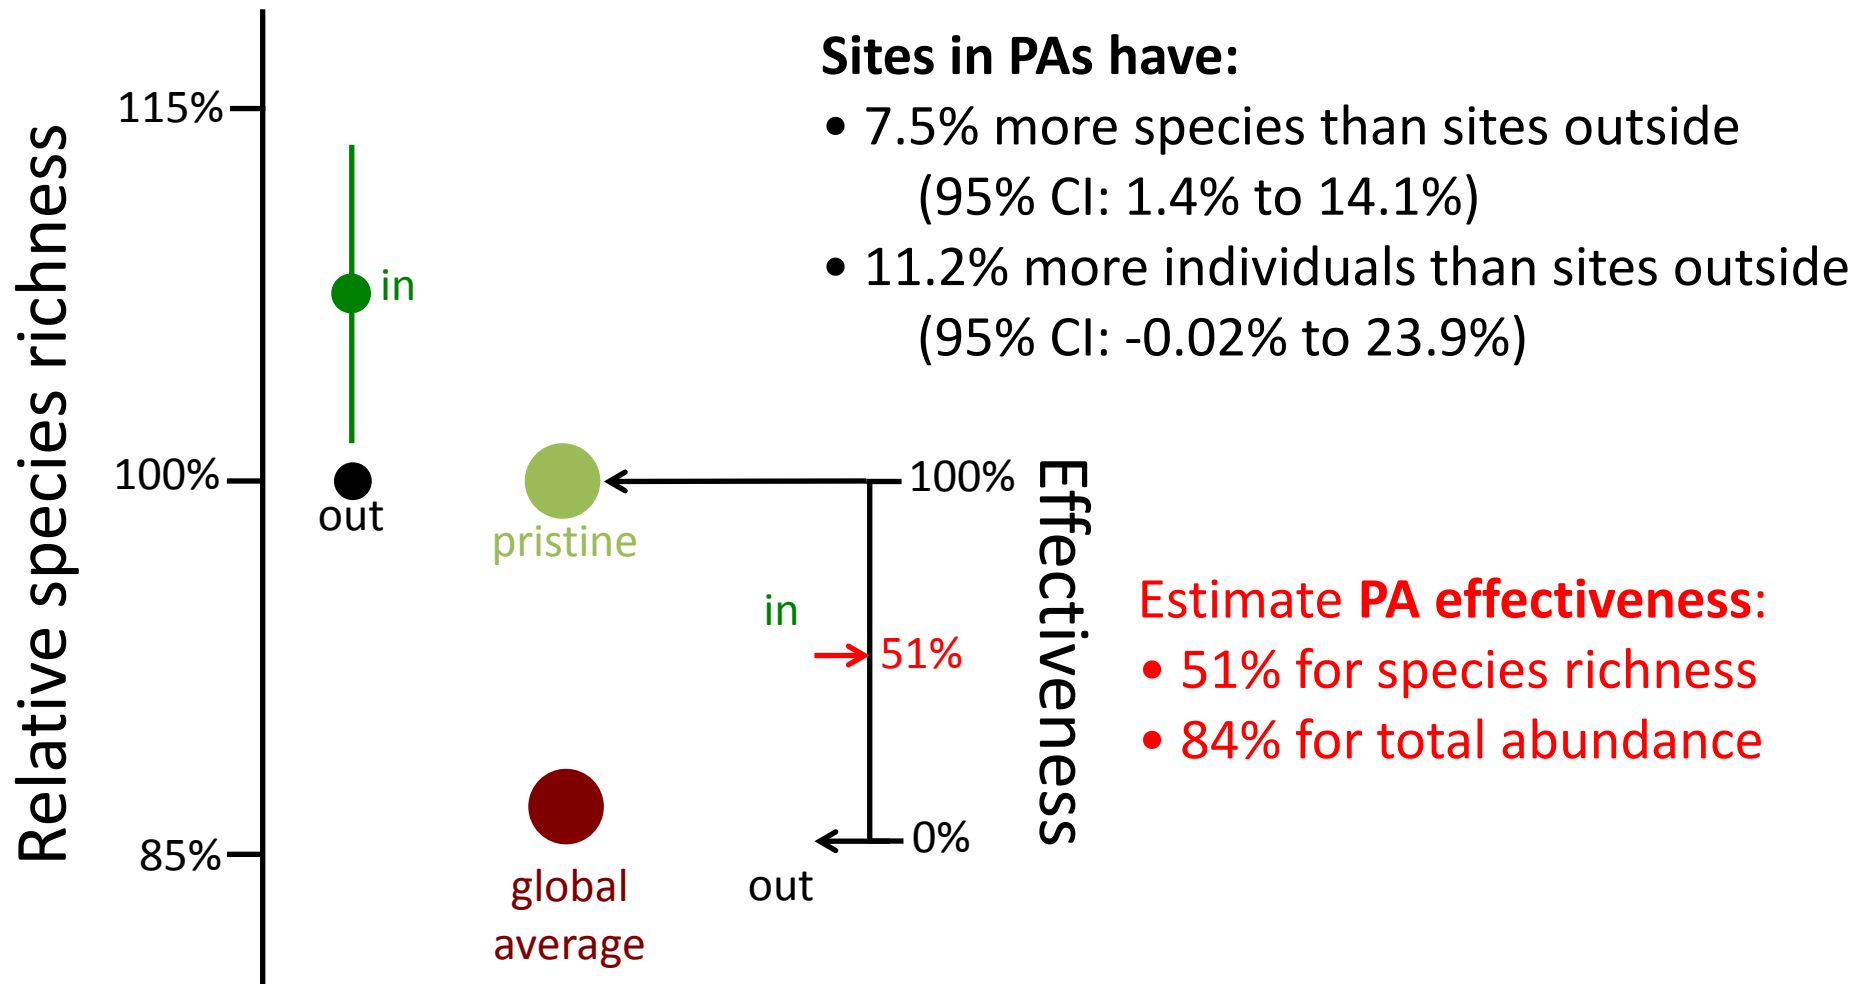

Site A

Site B

How effective are terrestrial PAs at retaining site-level biodiversity?

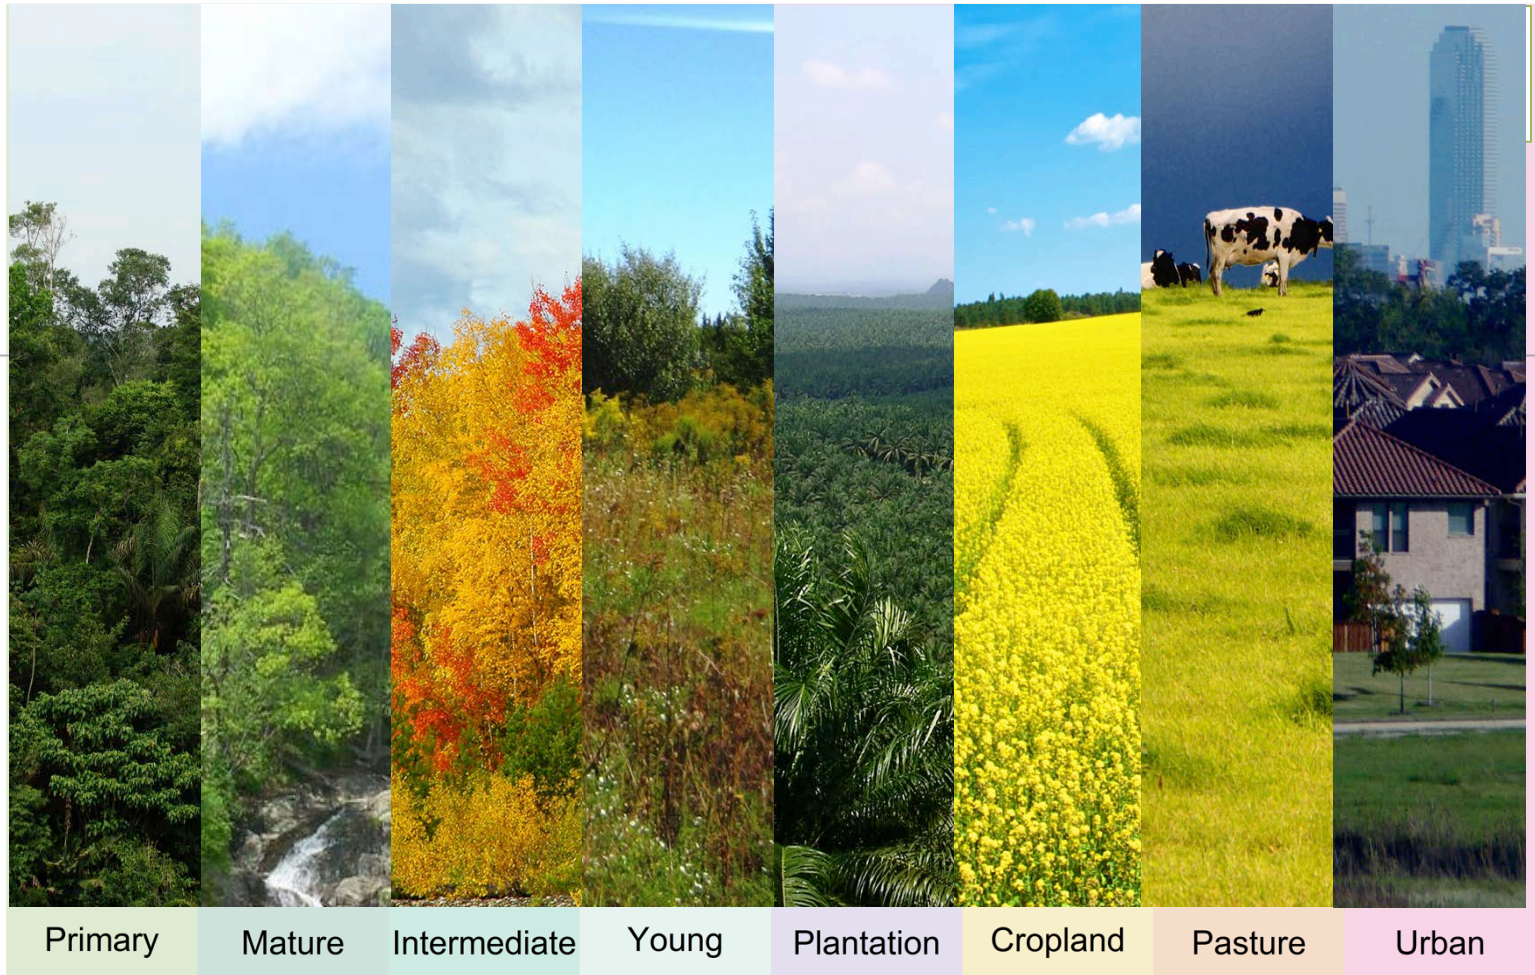

Land use and diversity outside PAs

Natural & semi-natural land uses

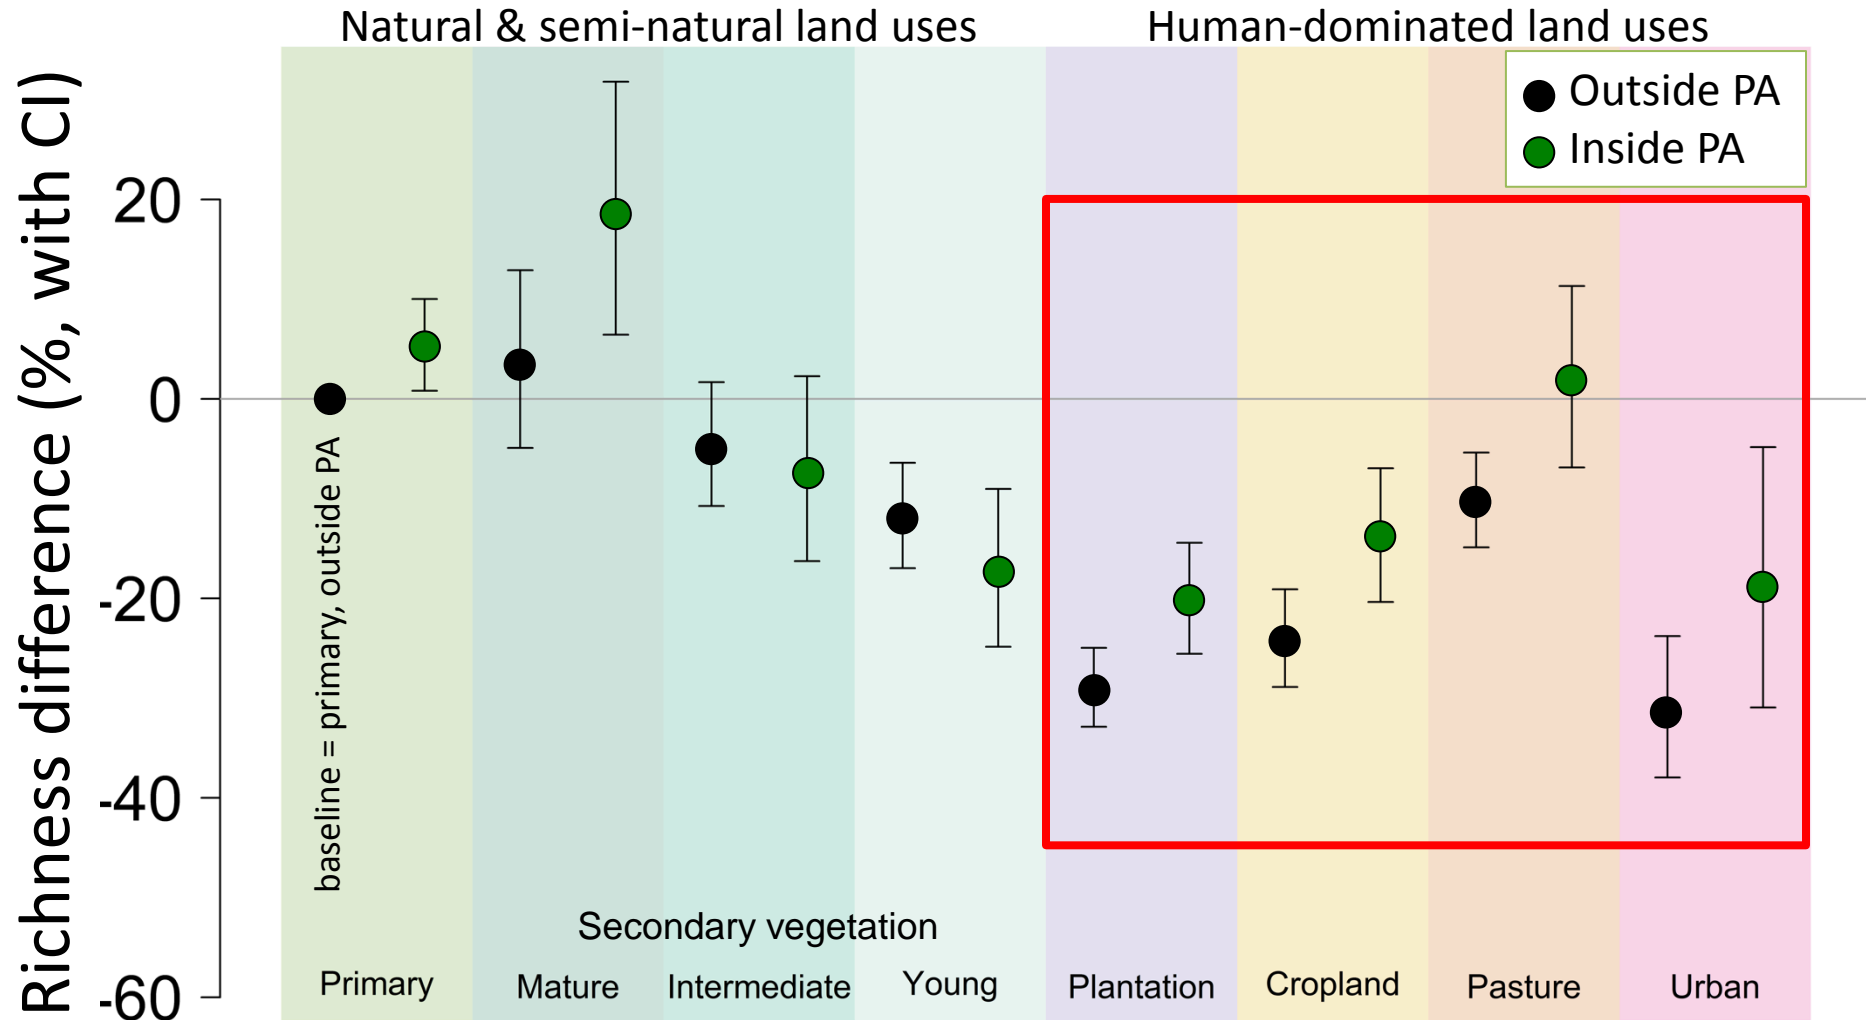

Human-dominated land uses

Richness difference (% , with CI)

20
0
-20
-40
-60

PAs mitigate land-use effects

... especially in tropics, and especially for invertebrates

What features of sites & PAs matter?

An aerial photograph of a river valley with a winding river. The landscape is a patchwork of agricultural fields in various shades of brown and tan, with some green areas. A semi-transparent grey rectangular box is overlaid on the left side of the image, containing text. Numerous red diamonds are scattered across the map, primarily along the river and in the upper right. Several grey crosses are located on the left side of the map, mostly in the lower half.

Site characteristics:

Agricultural suitability

Accessibility

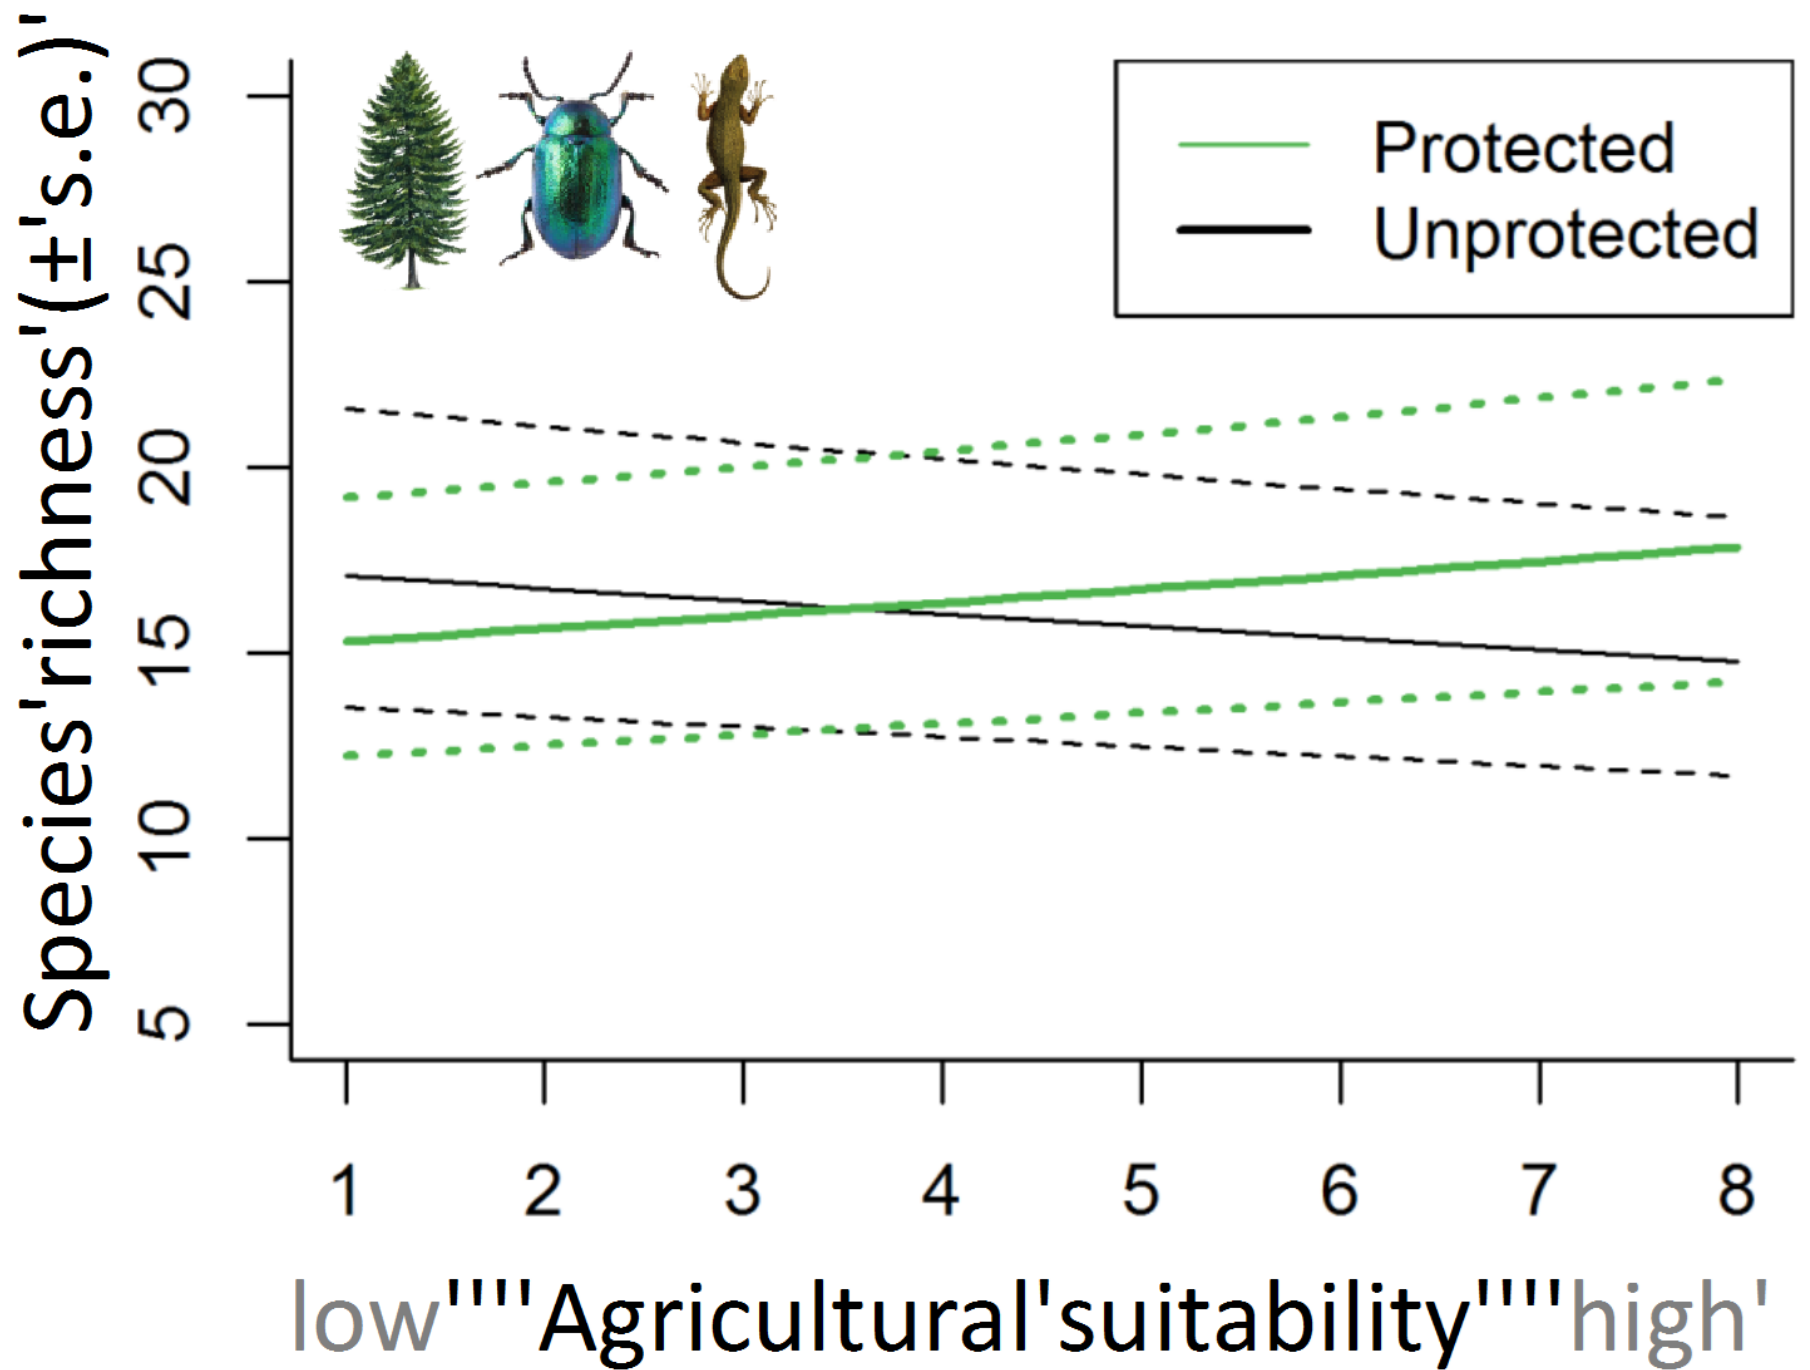

Distance to PA boundary

Human population density

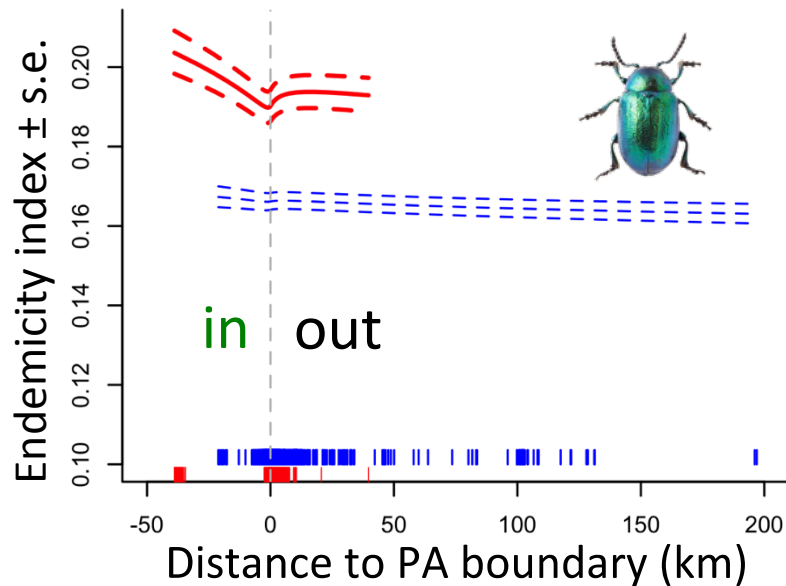

PA characteristics:

Duration of protection

Size

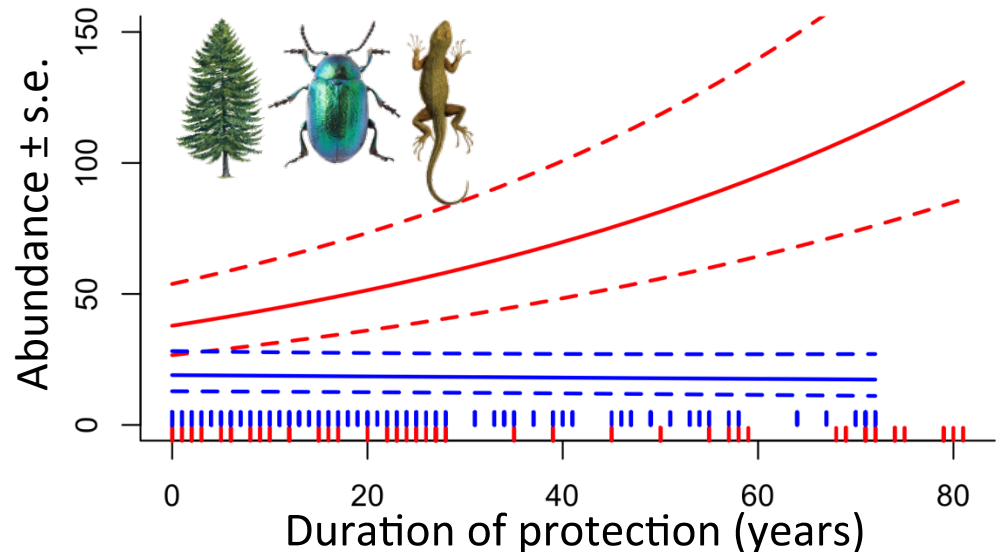

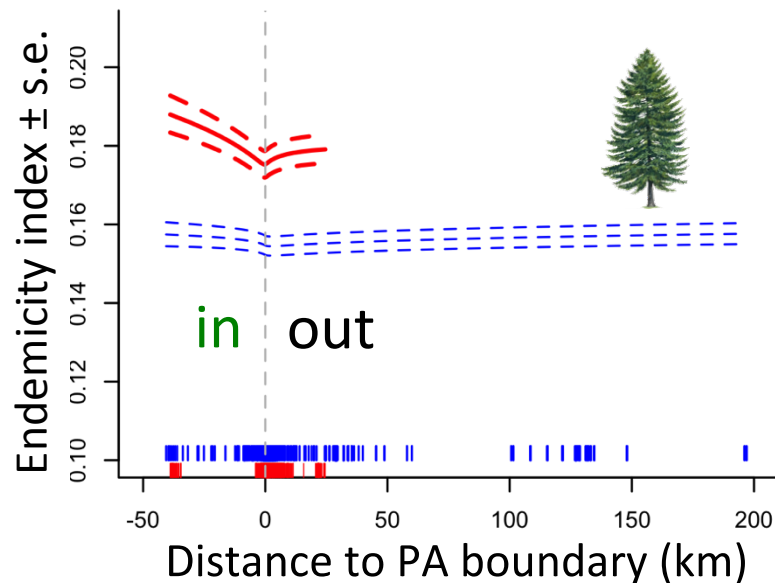

Tropical vs temperate

In the tropics:

- ← Invertebrate endemicity is higher further inside PAs (also richness)
- ↙ Botanical endemicity is higher further inside PAs (not richness)
- ↓ Abundance is higher in older PAs

- How effective are terrestrial Protected Areas?
 - **51%** for species-richness, **84%** for abundance
- Mitigate responses or just reduce pressures?
 - Mitigate responses to land-use change, esp. in tropics
 - Response to human population is same inside and out
- Where do PAs make most difference?
 - Tropics
 - Land suitable for agriculture
 - Large, long-established PAs
- Effects of PAs are strongly contingent
 - Vary widely among regions, land uses and taxa
 - Need taxonomic & geographic breadth to get full picture

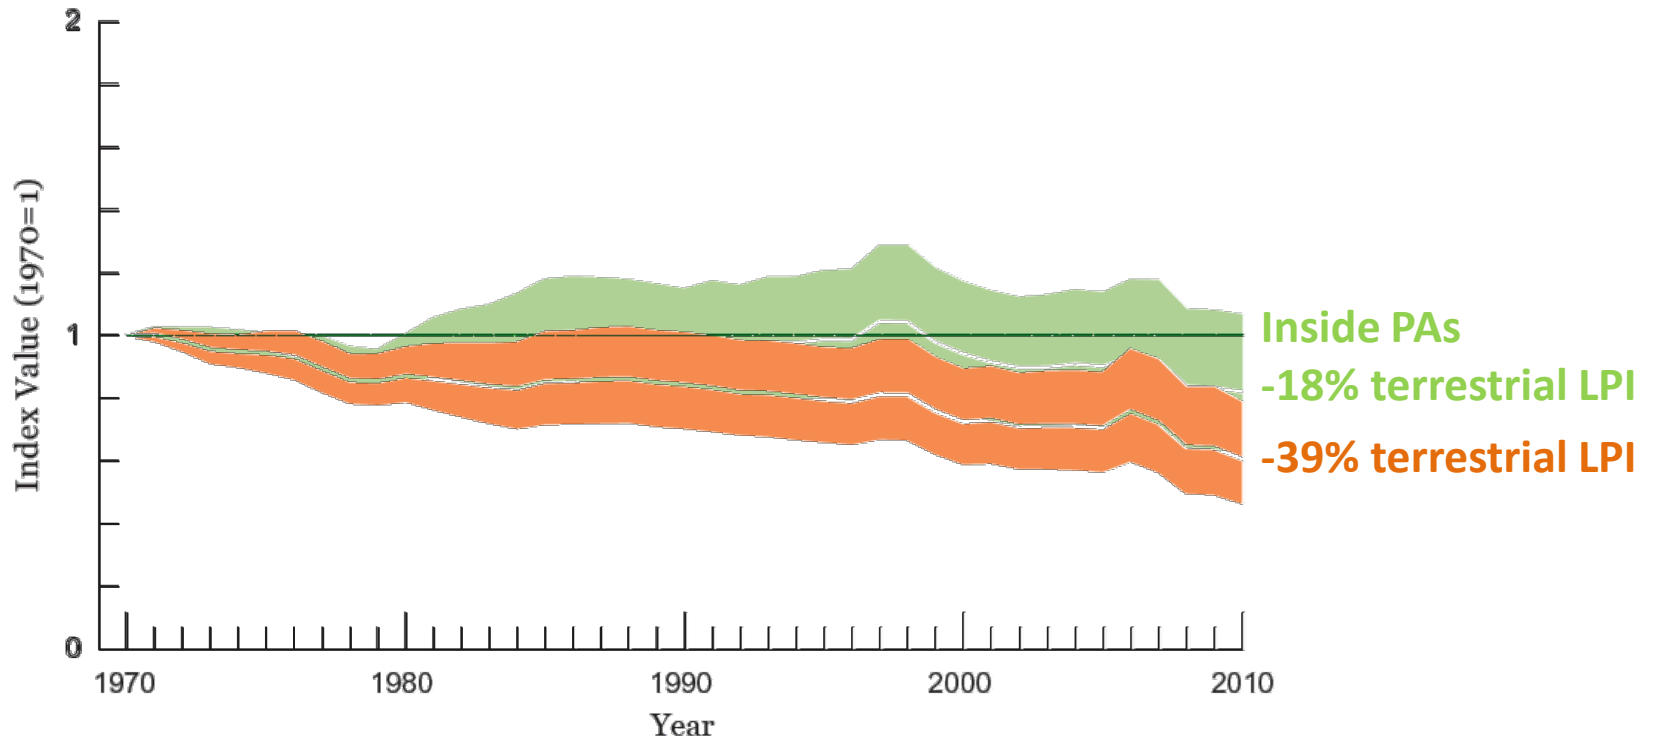

Any questions?

Species

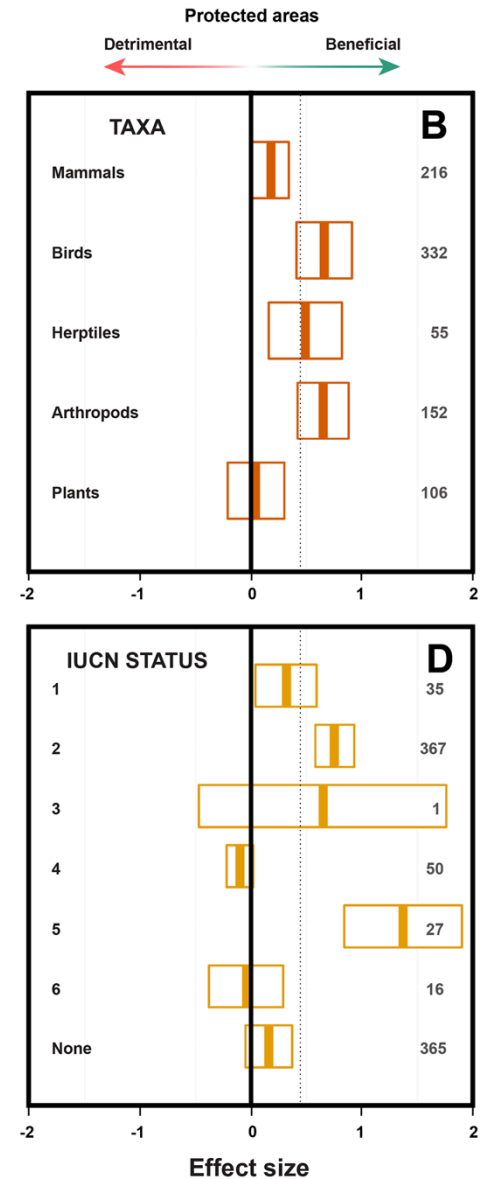

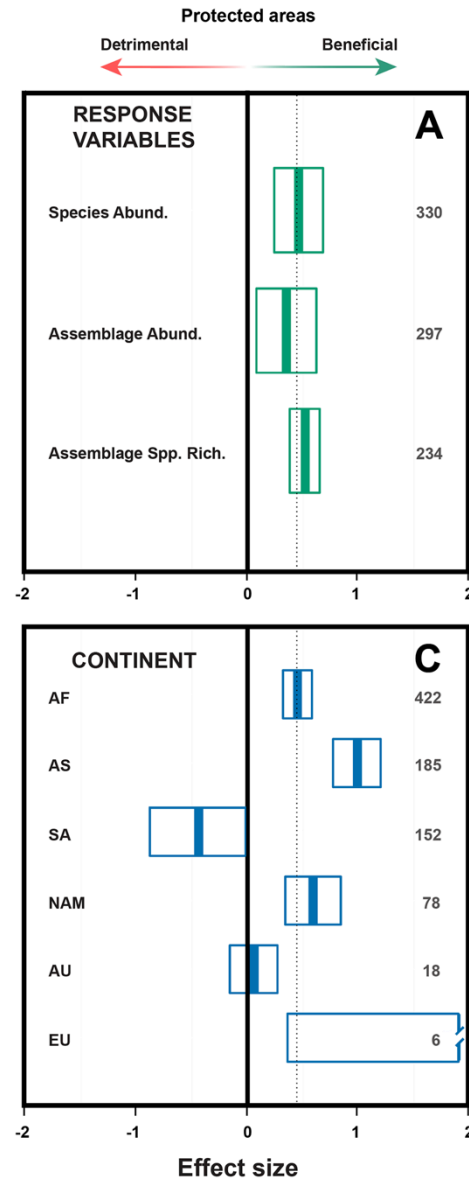

Inside/outside PAs: 1,956 / 4,182 populations;
773 / 1,562 mammal, bird, reptile, amphibian species

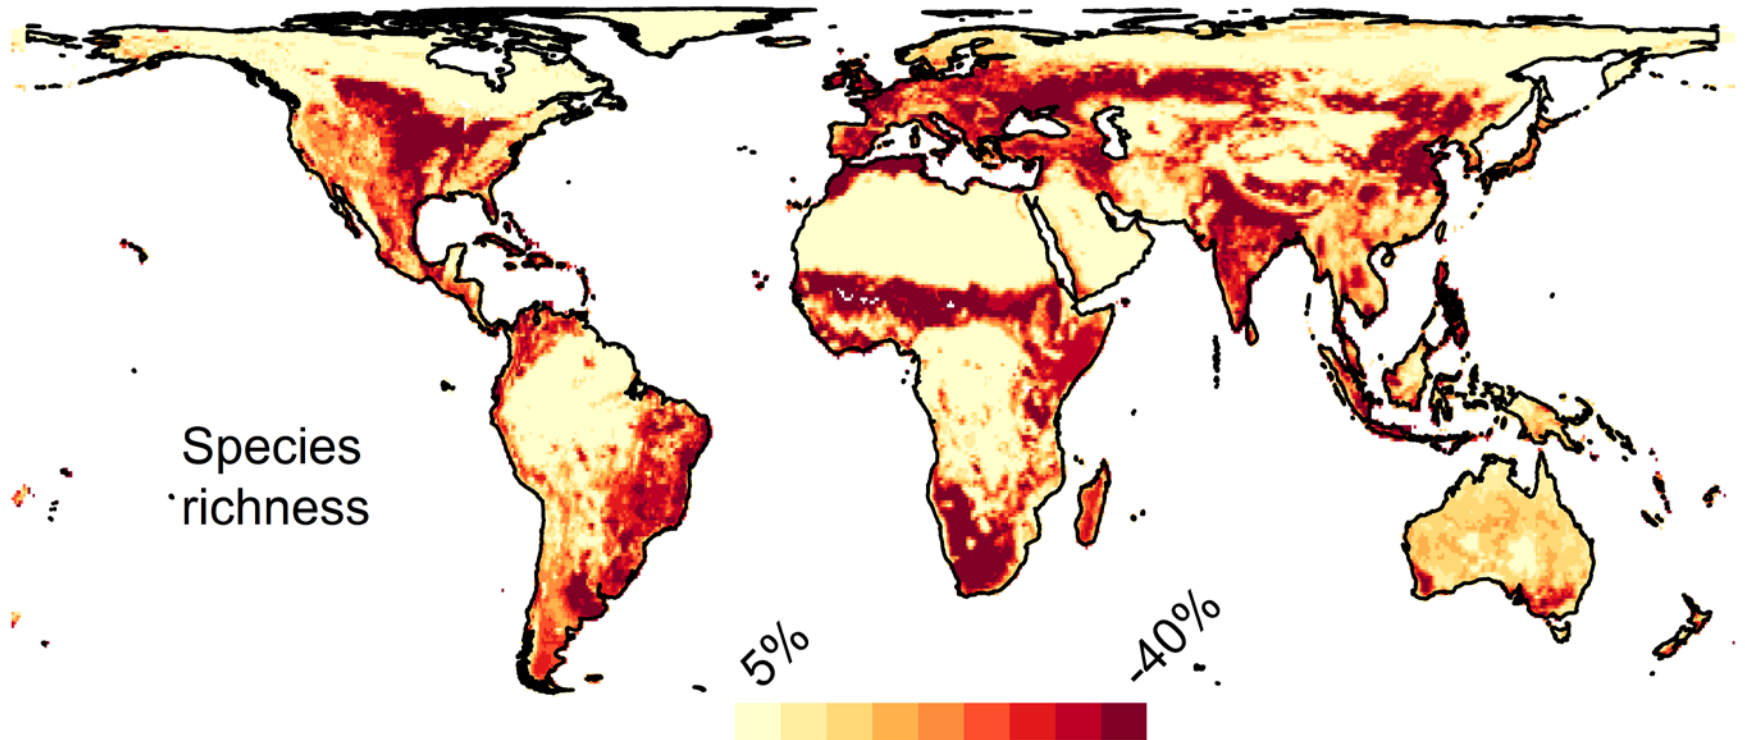

Species

86 sources
57 protected areas

Loss of species diversity to date

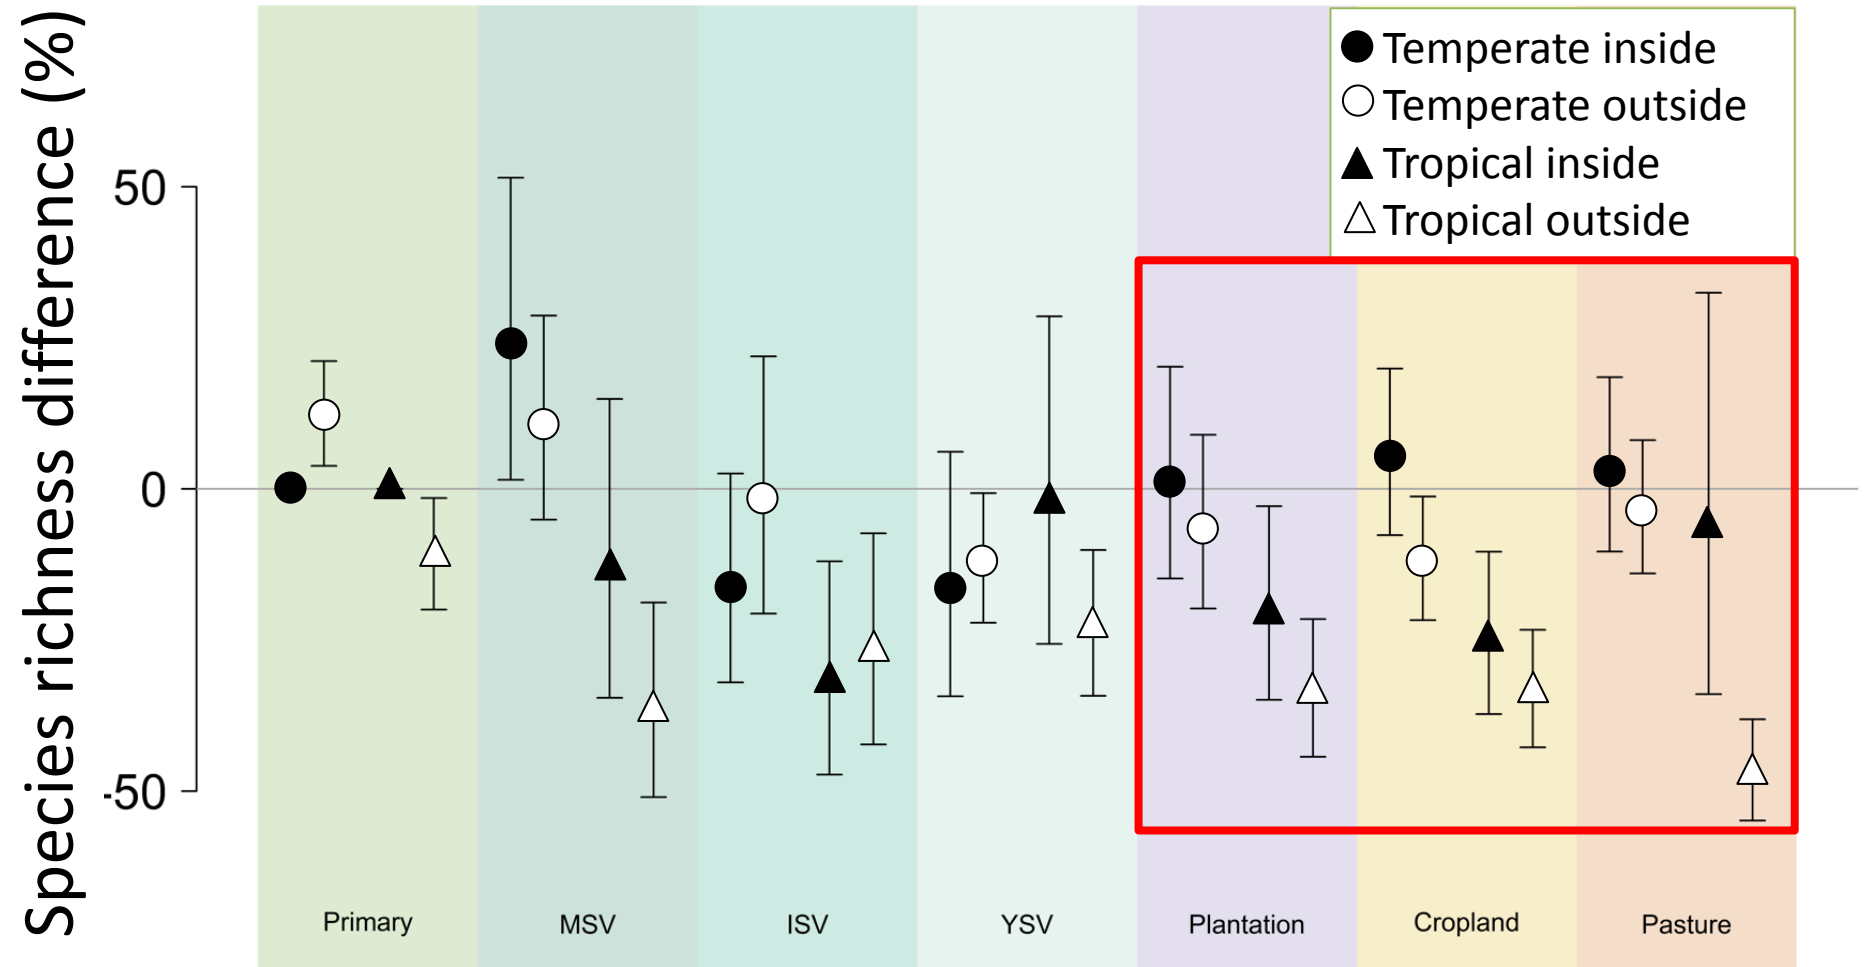

Newbold et al. (in revision)

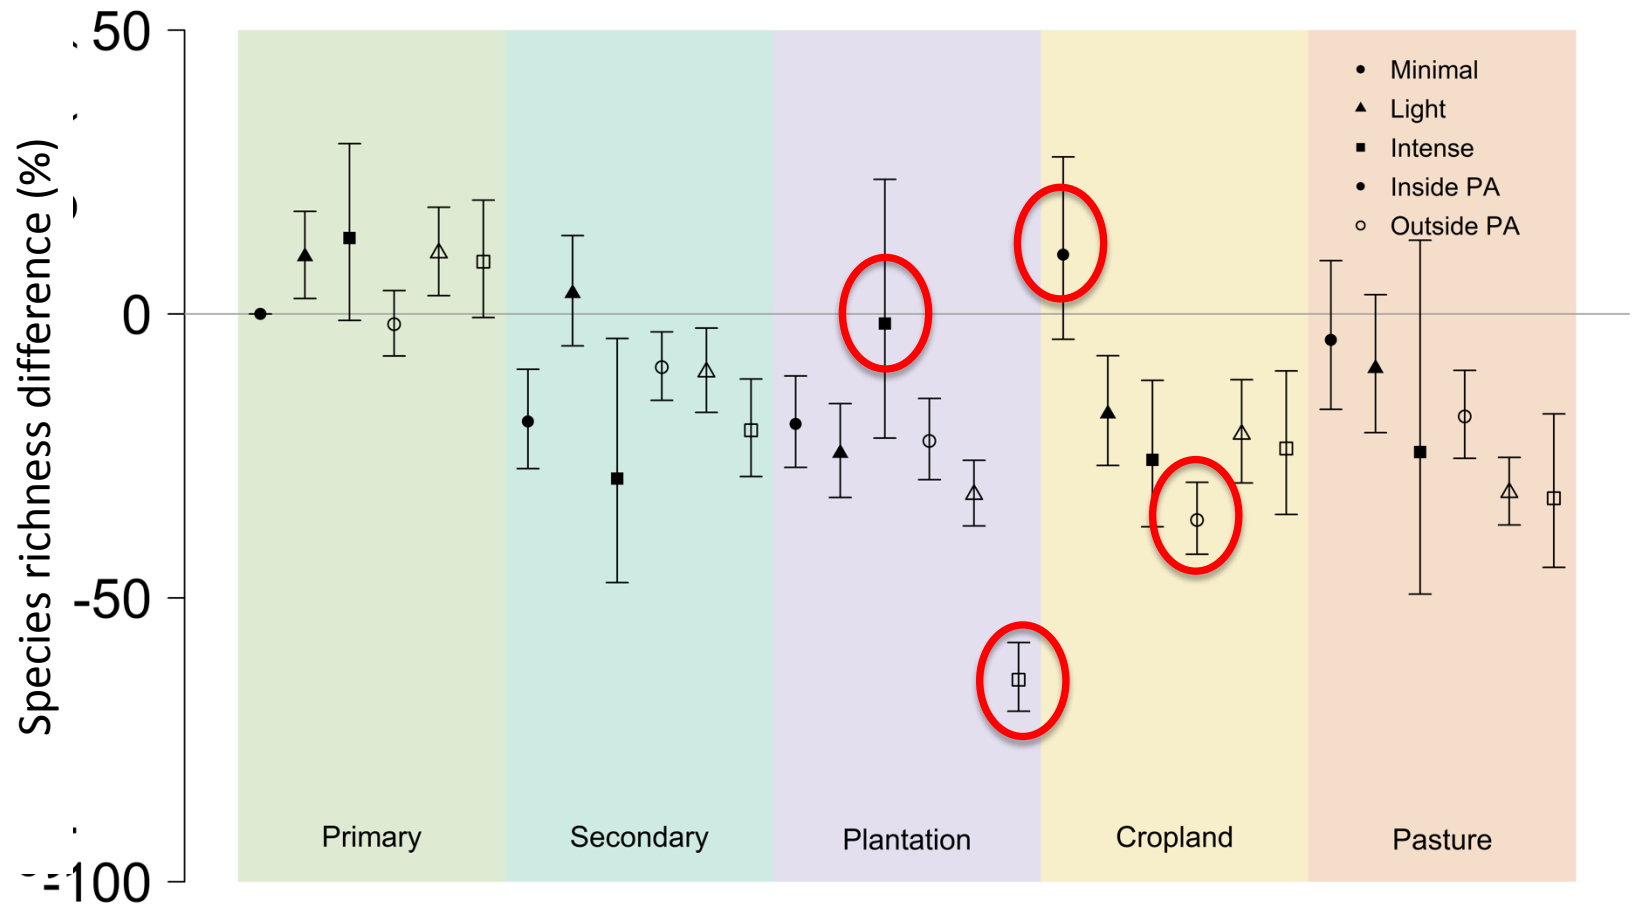

Coerce sites into matrix of land use classes and land use intensities

Land cover class	Minimal use	Light use	Intense use
Primary forest (forest composed of native vegetation, which is not known to have been destroyed during historical times)	Any threats identified are very minor (e.g., very light use) or very limited in the scope of their effect (e.g., hunting of a particular species of limited ecological importance).	One or more threats of moderate intensity (e.g., selective logging) or breadth of impact (e.g., bushmeat extraction), which are not severe enough to markedly change the nature of the ecosystem.	One or more threats that is severe enough to markedly change the nature of the ecosystem (e.g., clear-felling).
Primary non-forest
Mature Secondary Vegetation
Intermediate Secondary
Young Secondary Vegetation
Secondary Vegetation (indeterminate age)
Plantation forest
Cropland
Pasture
Urban

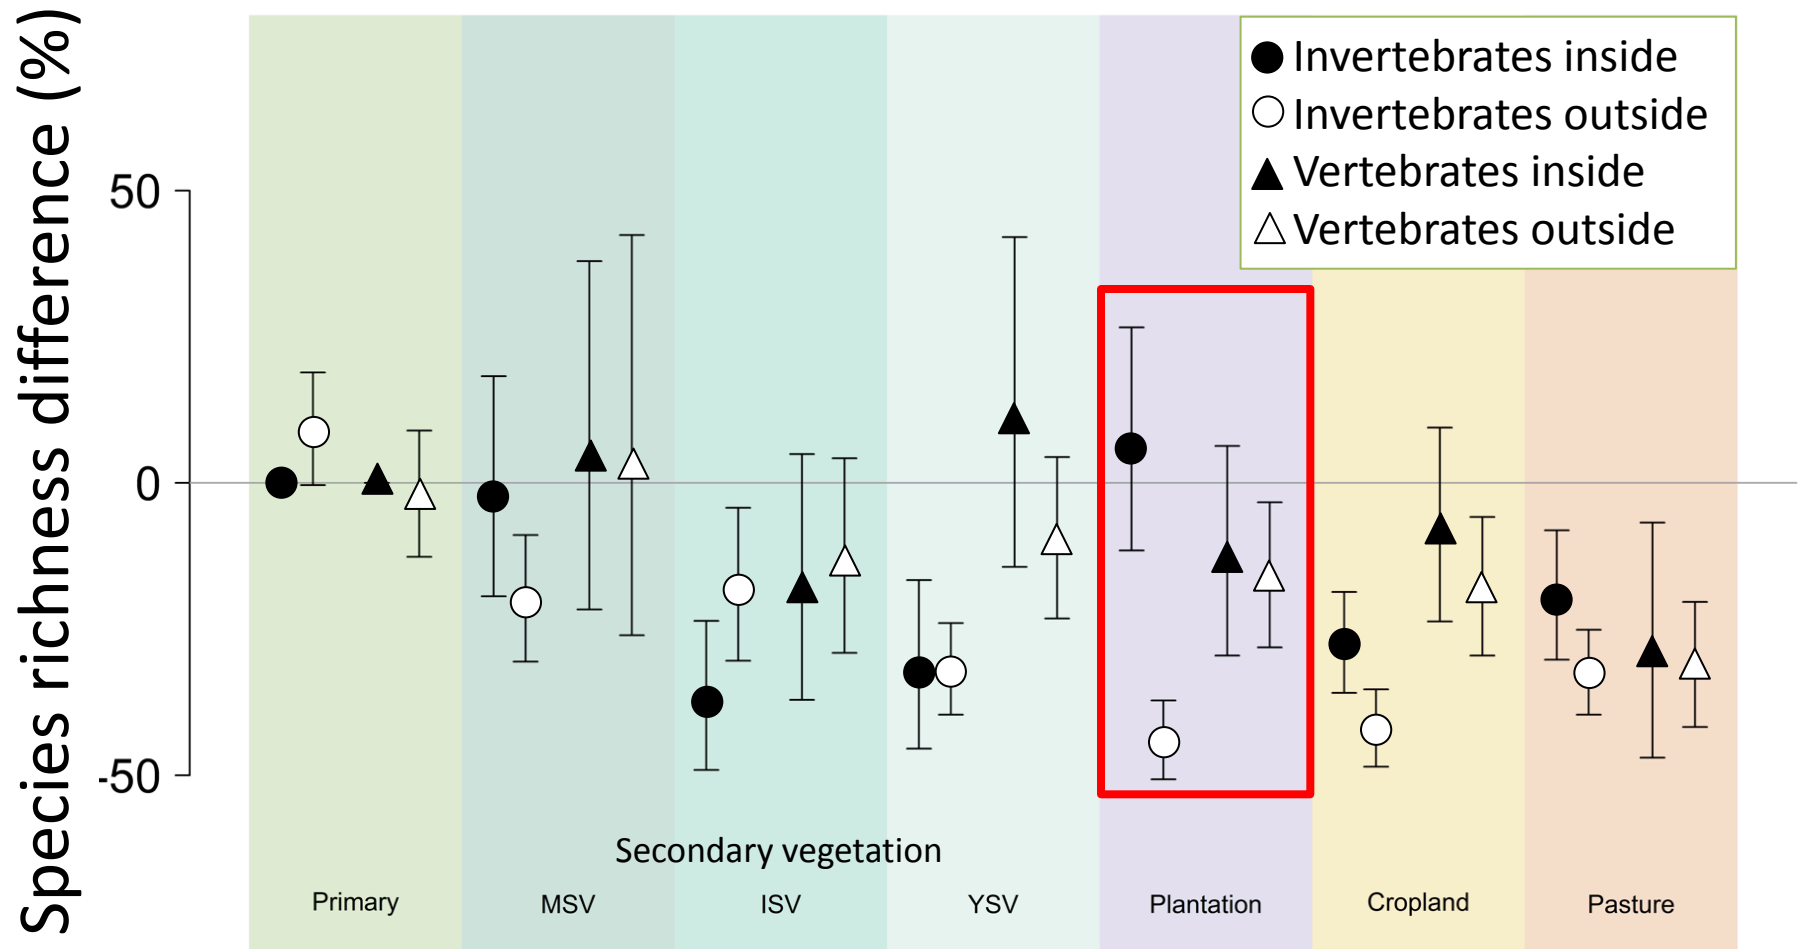

Land use has worse effects in tropics, but PAs there make more difference

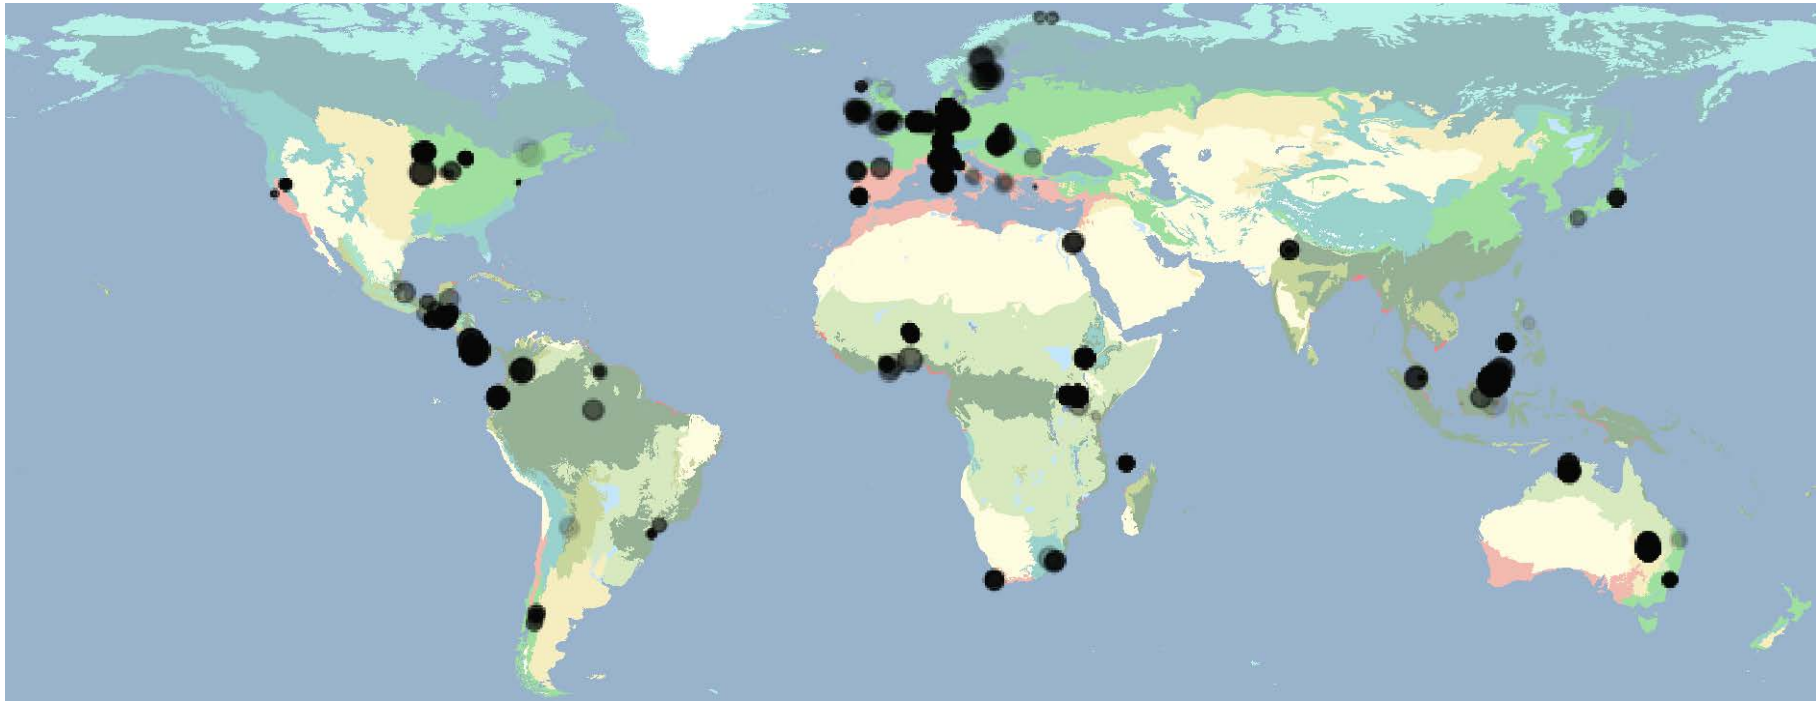

Given equal land-use intensity Protected Areas retain higher biodiversity, in most cases

Effect of PAs varies among taxa

The data set: matched land-use

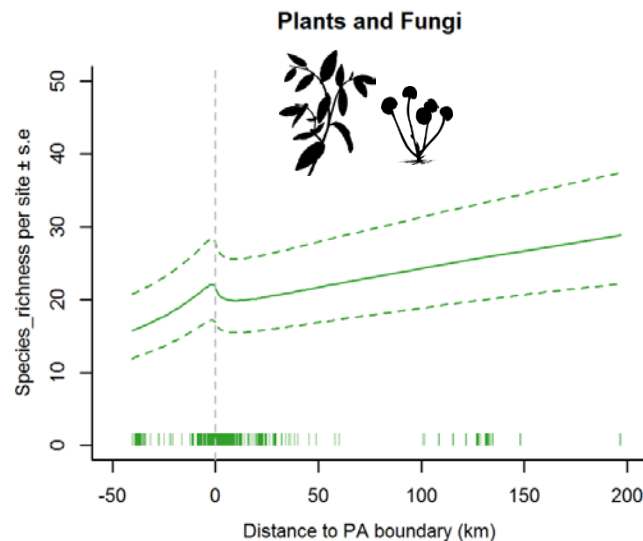

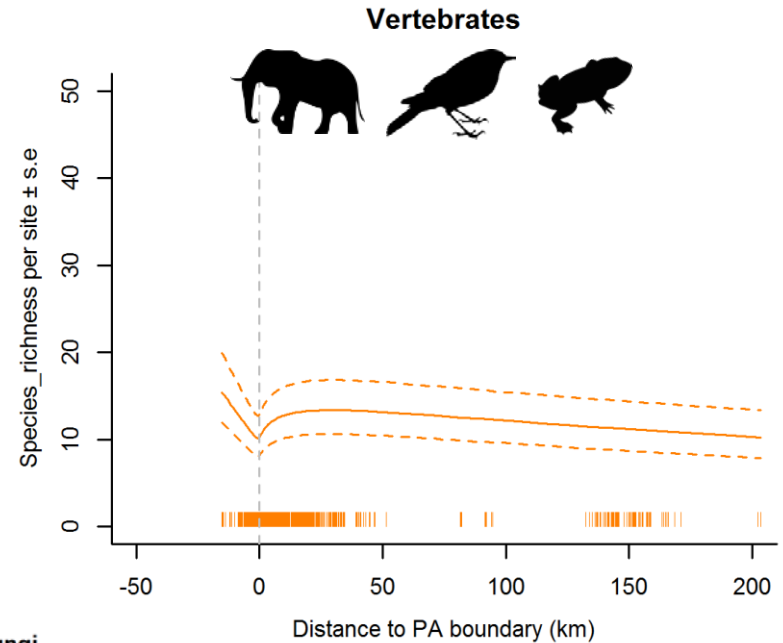

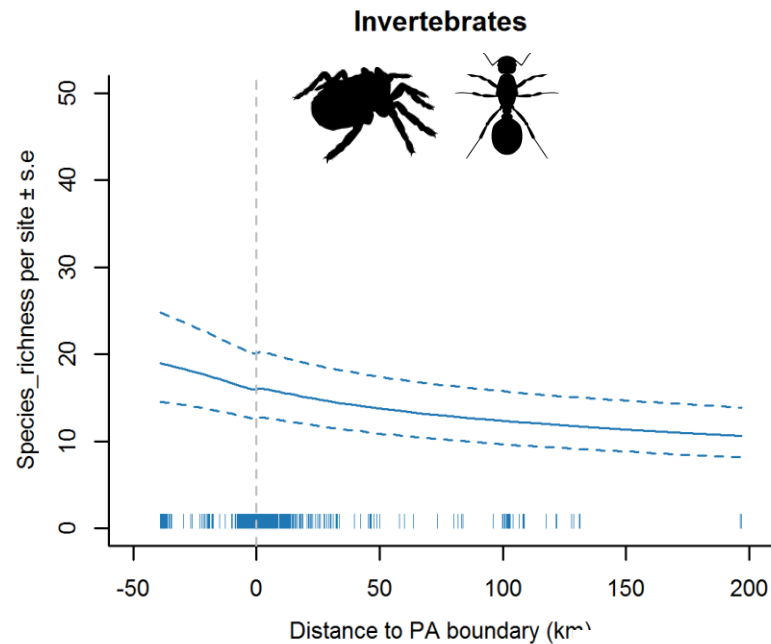

8,512 sites
48 countries
95 ecoregions

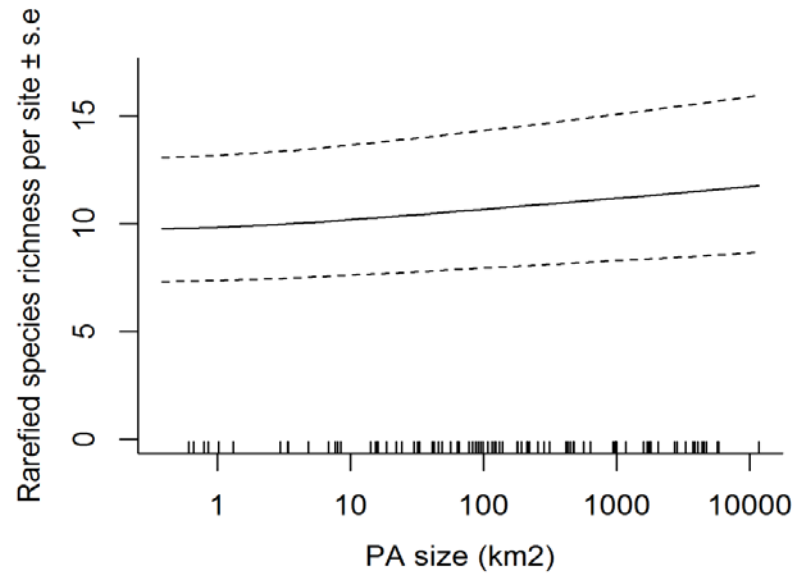

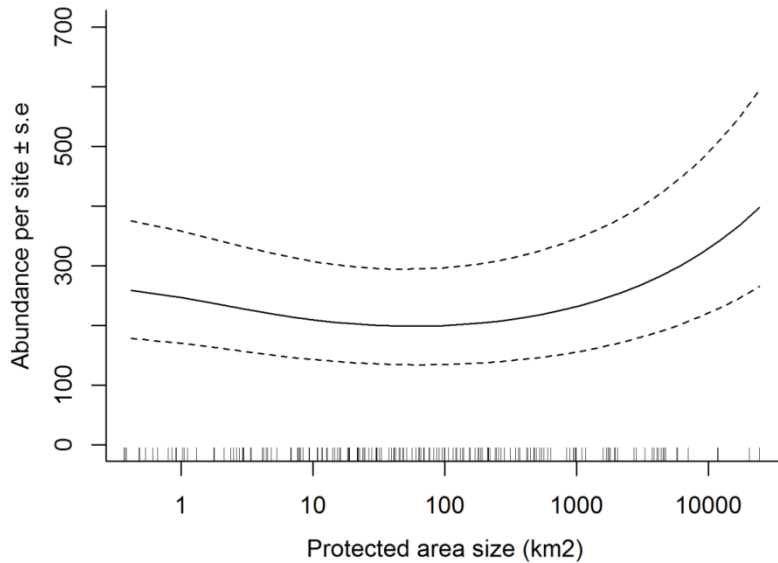

116 published sources
179 data sets
907,270 samples

17 hotspots
420 protected areas
15,656 taxa

Higher species richness of invertebrates and vertebrates further inside PAs

Does the size of the PA matter?

Yes, but no clear threshold size for recommendation
